# Outline

---

# Advantages and limitations of Li-ion and Ni-MH batteries

## Li-ion

✓ High energy density

✓ High power

X **Safety: flammable organic electrolyte**

- ↳ WiS electrolytes
- ↳ Na, Mg batteries

## Ni-MH

✓ Security and Robustness

✓ Low-cost

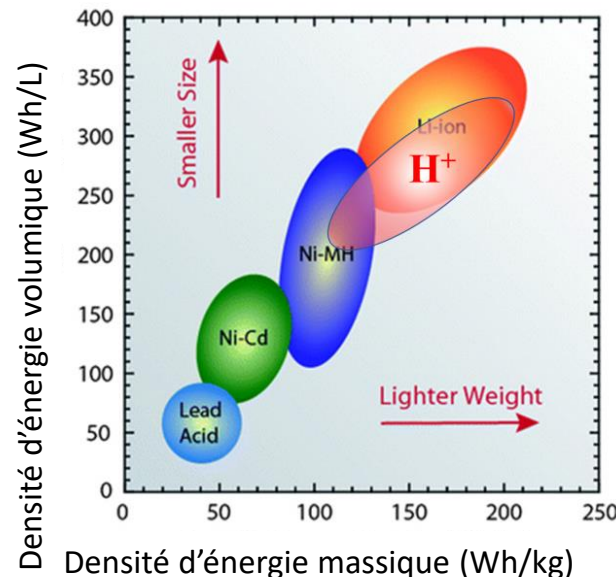

X **Energy density: narrow electrochemical window of water**

X **Lifetime : electrode corrosion in KOH solution**

↳ Protonic conducting battery in ionic liquid (IL) electrolyte:

Charge carrier: abundant, light-weight, enables a quick ionic conduction

Concept inspired from Ni-MH batteries but modifying the electrolyte and the negative and positive electrodes.

# Ionic liquids

- Salts that are liquid below 100°C
- Their physical and chemical properties can be tailored by mixing them with other compounds [1]
- Nonflammable, non-volatile and recyclable

⇒ Safe electrolyte

- Two families: aprotic and protic (PIL)
- PIL = mobile proton with conductivity above 1 mS.cm<sup>-1</sup> [2]

⇒ Possible application as proton exchange electrolyte

- Wide electrochemical window

⇒ High cell potential enabling high energy density  $W = Q \times U$

capacity      voltage

| [EMIM][Ac]+Ac(2M)     | 50.9                      | 31.51                                  | 5.72  | 15.85                                    | 3.0                        |

- The medium with low viscosity provides high conductivity!
- Electrochemical window wider than that of KOH aqueous solution

# Half cell test: working electrode

Active material:  $AB_5$  -type alloy

$$a = 5.0086 \text{ \AA}$$

$$c = 4.0026 \text{ \AA}$$

S.G.  $P6/mmm$

Composite electrode formulation:

- 90 wt. % alloy (active material)
- 5 wt. % carbon black (conductor)
- 5 wt. % PTFE (binder)

# Half cell test: galvanostatic cycling

## 3-electrode electrochemical cell:

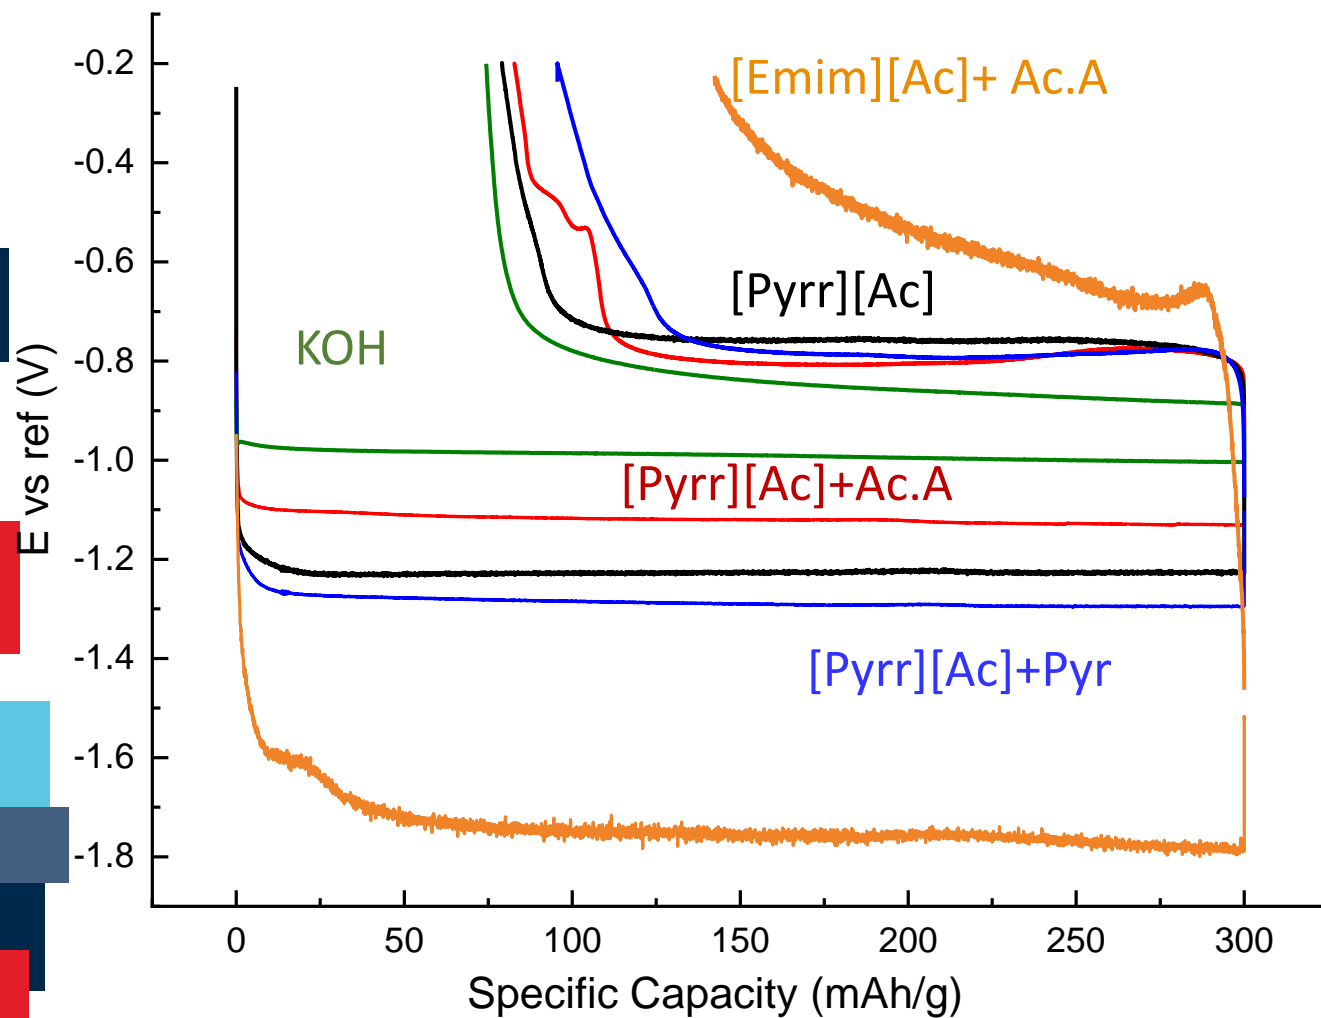

- **Working electrode: composite  $AB_5$**  pressed on a Ni-grid
- **Reference electrode:** Hg/HgO for KOH solution, Ag/AgNO<sub>3</sub> for ILs
- **Counter electrode:** Platinum grid

## Galvanostatic cycling regime:

- C/40 for ILs
- C/10 for KOH solution

# Half cell test: galvanostatic cycling

# Half cell test: galvanostatic cycling

# Half cell test: galvanostatic cycling

## Capacity vs cycle number:

- The highest capacity is obtained in KOH medium after activation cycles
- For IIs, capacity increases as  $[\text{Pyrr}][\text{Ac}] + \text{Pyr} < [\text{Pyrr}][\text{Ac}] + \text{Ac.A} < [\text{Pyrr}][\text{Ac}]$
- The lowest capacity is observed for  $[\text{Emim}][\text{Ac}] + \text{Ac.A}$ , and it decreases rapidly
- $[\text{Pyrr}][\text{Ac}]$  shows the best properties. It will be further investigated

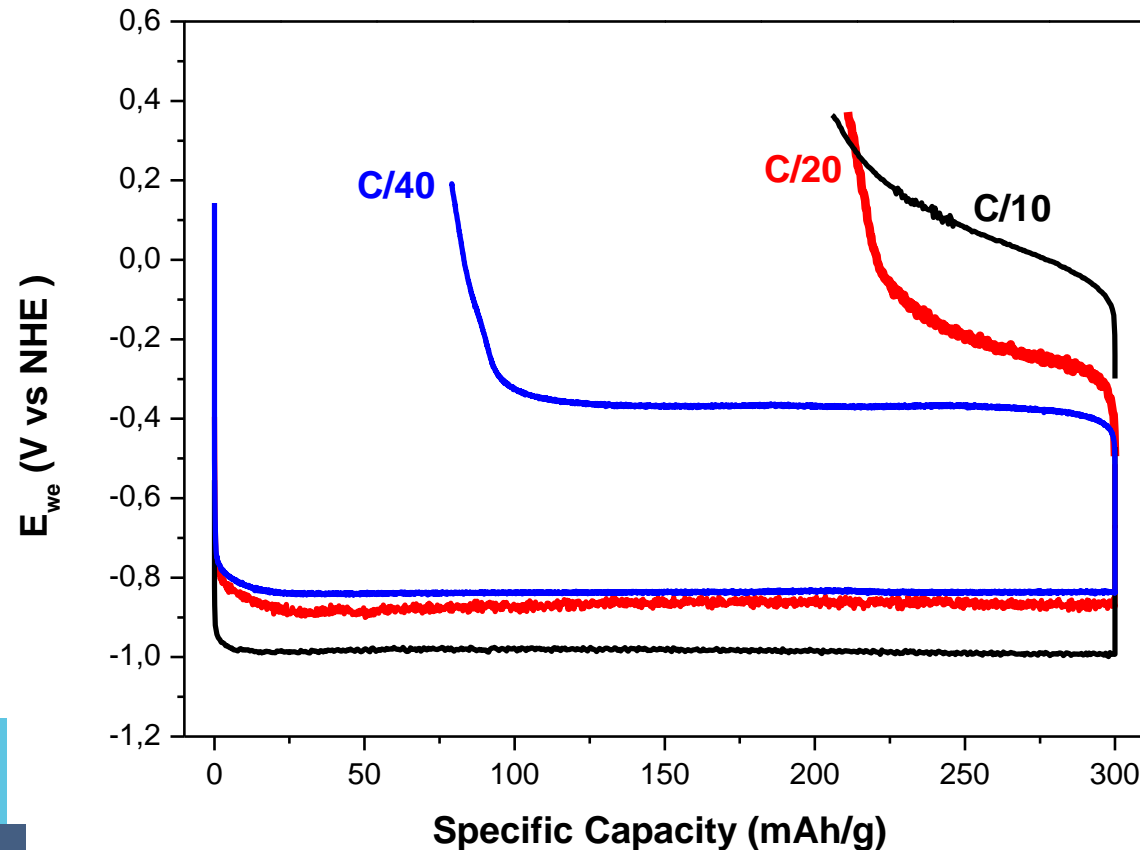

# Half cell test: galvanostatic cycling

| Medium                  | 1 <sup>st</sup> cycle capacity (mAh.g <sup>-1</sup> ) | Maximum capacity (mAh.g <sup>-1</sup> ) | 8 <sup>th</sup> cycle's capacity (mAh.g <sup>-1</sup> ) | Capacity decrease |
|-------------------------|---|---|---|-------------------|
| KOH                     | 206   | 254                                     | 229   | 10 %              |
| [Pyrr][Ac]              | 202   | 221                                     | 215   | 3%                |
| [Pyrr][Ac] + Ac.A. (2M) | 217   | 217                                     | 191   | 12 %              |
| [Pyrr][Ac] + Pyrr (2M)  | 201   | 204                                     | 185   | 9 %               |
| [EMIM][Ac] +Ac(2M)      | 189   | 189                                     | 117   | 38 %              |

## Maximum capacity and capacity decrease:

- The highest capacity is obtained in KOH medium after activation cycles
- For IIs, capacity increases as  $[\text{Pyrr}][\text{Ac}] + \text{Pyr} < [\text{Pyrr}][\text{Ac}] + \text{Ac.A} < [\text{Pyrr}][\text{Ac}]$
- The lowest capacity is observed for  $[\text{Emim}][\text{Ac}] + \text{Ac.A}$ , and it decreases rapidly
- [Pyrr][Ac] shows the best properties. It will be further investigated

# Half cell test: galvanostatic cycling

$AB_5$  in [Pyrr][Ac] at different C-rates:

- Charge potential changes little
- Discharge potential strongly increases with C-rate
- Reversible capacity decreases with C-rate
- Kinetic limitation of charge transport?

# XRD of electrode after charge: evidence of hydrogen transfer

- XRD of the charged electrode containing the  $\text{AB}_5\text{H}_6$  hydride phase
- MH releases some hydrogen spontaneously
- MH amount decreases with measuring time and finally convert into the intermetallic  $M$  phase

# Conclusions and prospects

- [Pyrr][F] and [Pyrr][Ac] have been synthesized, their mixtures with acetic acid and pyrrolidine have been studied as electrolytes for proton exchange batteries.
- An  $AB_5$ -type alloy has been cycled with ILs. A specific capacity of  $216 \text{ mAh}\cdot\text{g}^{-1}$  was obtained in [Pyrr][Ac]
- Obtained results are promising with a capacity close to that obtained in KOH medium
- The XRD of the charged electrode confirms that electrochemical cycling leads to the hydrogenation and dehydrogenation of the intermetallic compound.
- Further question may be raised for the electrolyte, the electrode/electrolyte interface.
- Positive side: to be explored
